

Weight-7: independent confirmation

All circuits: $[[56, 12, 7]]$, $R=7$ noisy rounds plus two ideal closing rounds; idle noise=0.
 Same-shot joint X/Z, full correlated DEM, Tesseract beam=2. $q=1-(1-F_{\text{joint}}/N)^{(1/(12 R))}$.
 q is an equivalent normalization of the block rate, not a measured per-qubit marginal.
 Bars: nominal Wilson 1-sigma intervals. Open symbols: precision target not reached.
 Downward arrows: zero-failure upper limits. Only finished points are shown.
 Historical selection data are excluded. Sequential stopping does not ensure nominal coverage.
